## Data analysis for odor from digestate experiments

Sasha D. Hafner

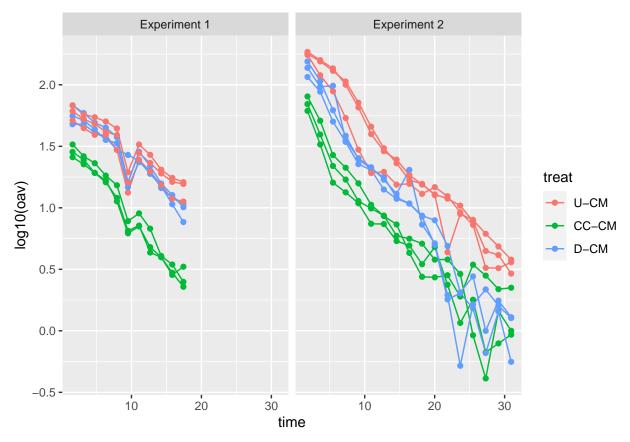

01 December, 2022

## Plots

```
ggplot(dat, aes(time, oav, colour = treat, group = interaction(rep, treat))) +
  geom_line() +
  geom_point() +
  facet_wrap(~ exper)
```

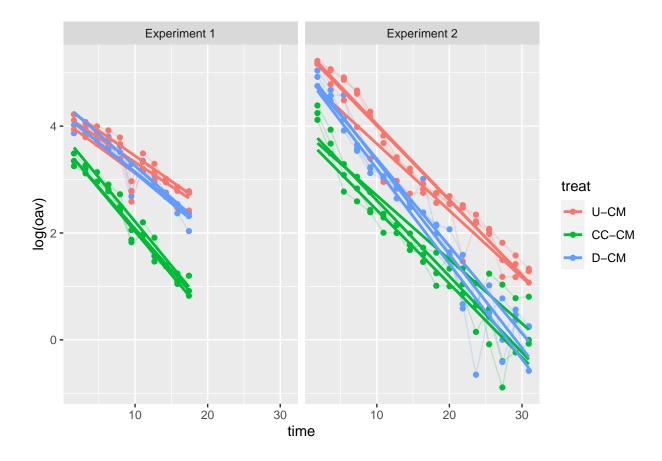

```
ggplot(dat, aes(time, log10(oav), colour = treat, group = interaction(rep, treat))) +
  geom_line() +
  geom_point() +
  facet_wrap(~ exper)
```

Looks linear enough.

```
ggplot(dat, aes(time, log(oav), colour = treat, group = interaction(rep, treat))) +
   geom_line(alpha = 0.2) +
   geom_point() +
   geom_smooth(method = lm, se = FALSE) +
   facet_wrap(~ exper)
```

## `geom\_smooth()` using formula 'y ~ x'

## Stats

So, our question will be (referring to last plot above) "are there differences in slope and initial value?". I had expected to use the intercept and slope terms in the analysis, but the least-squares lines don't fit very well in all cases at the start. And anyway, the initial measurements are our best estimate of initial OAV.

Set reference to untreated cattle manure.

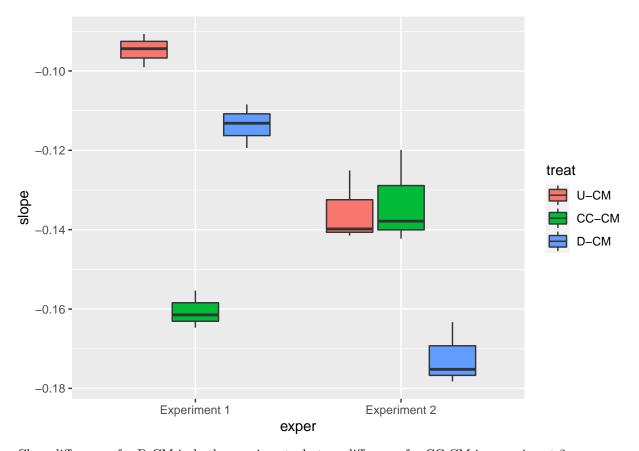

```
dat$treat <- factor(dat$treat, levels = c('U-CM', 'CC-CM', 'D-CM'))
dat$exper <- factor(dat$exper)</pre>
```

Unit of analysis will be wind tunnel plot.

First fit linear model to each wind tunnel to get the slopes.

Take a look at slopes.

```
ggplot(lmods, aes(exper, slope, fill = treat)) +
geom_boxplot()
```

Clear differences for D-CM in both experiments, but no difference for CC-CM in experiment 2.

Now analysis.

Look at slope.

```
modslope1 <- lm(slope ~ treat * exper, data = lmods)</pre>

Use this model in paper. Both D-CM and CC-CM have lower slope than reference in experiment 1.
Results are a first-order constant with units of 1/hr that describes the drop in flux over time. Note that
log() (not log10()) used above gives this result.
Experiment 2 next.

Here only D-CM is lower, and the effect seems larger than in experiment 1. Use this model in paper for experiment 2.

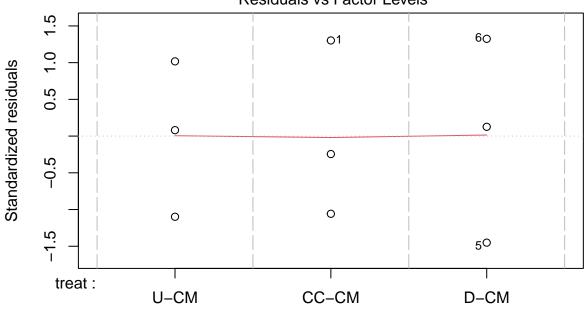

Diagnostic plots.

```
plot(modexp1, ask = FALSE)
```

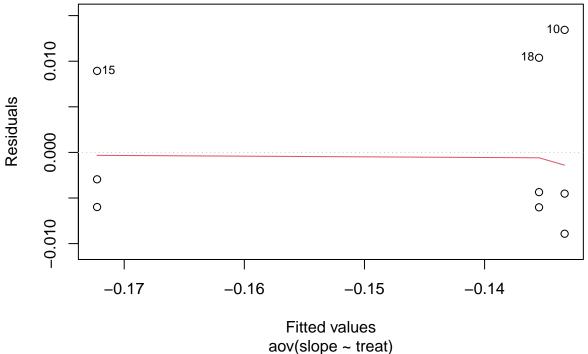

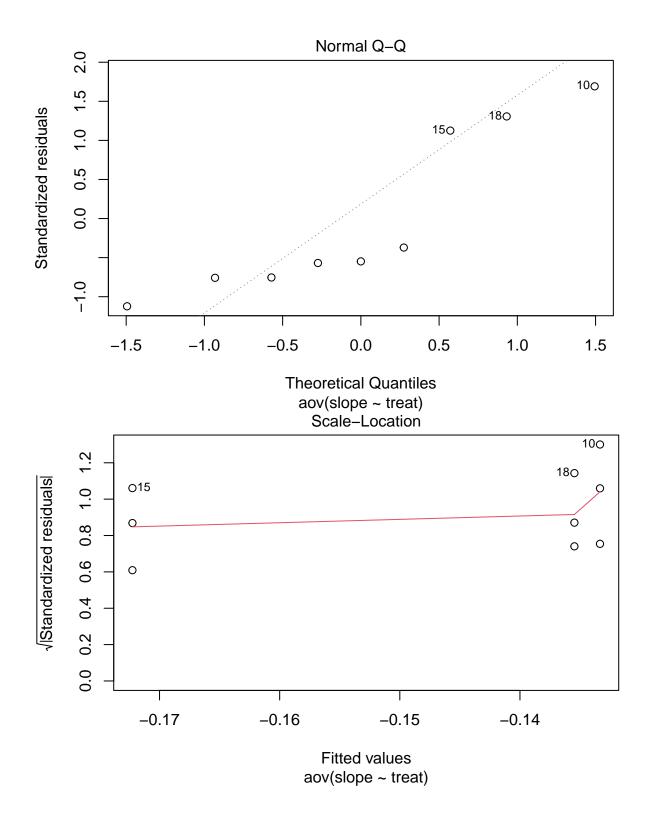

Factor Level Combinations

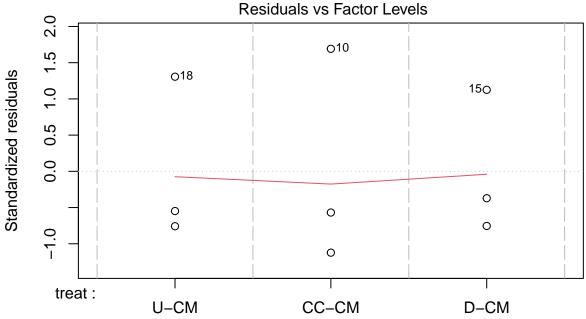

plot(modexp2, ask = FALSE)

**Factor Level Combinations** 

Not terrible.

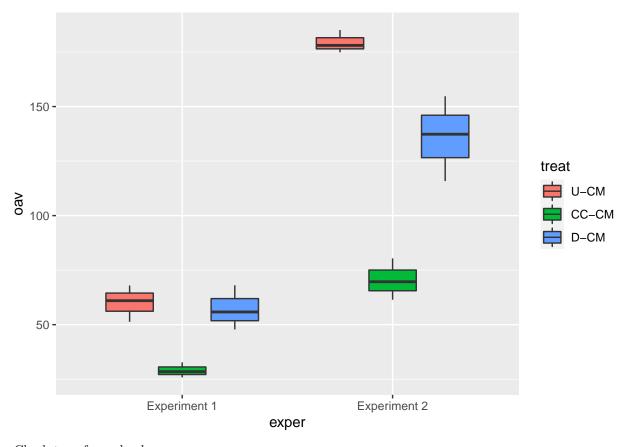

Now look at first measurement period in lieu of intercept.

Add interval number to data.

```
dat <- dat[, int := as.integer(factor(time)), by = exper]</pre>
```

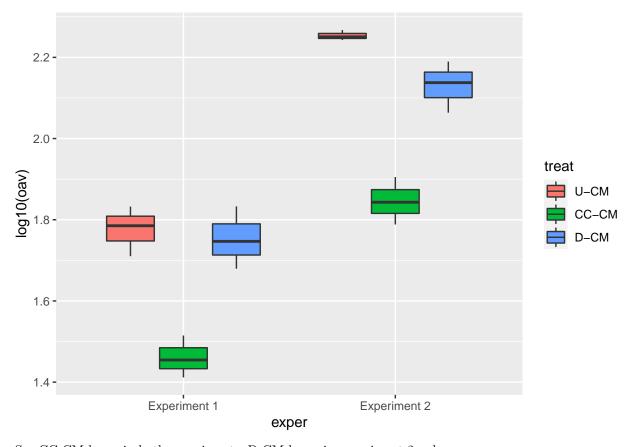

And take a look at the initial OAV values.

```
dd <- subset(dat, int == 1)
ggplot(dd, aes(exper, oav, fill = treat)) +
  geom_boxplot()</pre>
```

Check transformed values.

```
ggplot(dd, aes(exper, log10(oav), fill = treat)) +
  geom_boxplot()
```

See CC-CM lower in both experiments, D-CM lower in experiment 2 only.

```
